

circles = all-CMRT arms (blue = cellulose, teal = amylose); no column beats a shuffle
stars = selector-aligned arms, which use only CMRT Cellulose-a as training data
$R^2 < 0$ means worse than predicting the mean
shuffled-target control, OD-RH aligned -0.756 ± 0.157 (5 repeats);
six-column control -0.465 ± 0.284 (one shuffle per column,
so this is a between-column spread rather than a permutation SD)
